Progressive terminology commitment

Arm values inclusive communities. Arm recognizes that we and our industry have used terms that can be offensive. Arm strives to lead the industry and create change.

We believe that this document contains no offensive terms. If you find offensive terms in this document, please email **terms@arm.com**.

Contents

1 Introduction

1.1 Product revision status

The rxpy identifier indicates the revision status of the product described in this book, for example, r1p2, where:

rx

>Identifies the major revision of the product, for example, r1.

Py

>Identifies the minor revision or modification status of the product, for example, p2.

1.2 Intended audience

This guide is intended for developers who want to learn about the Scalable Vector Extension version two (SVE2).

1.3 Conventions

The following subsections describe conventions used in Arm documents.

1.3.1 Glossary

The Arm Glossary is a list of terms used in Arm documentation, together with definitions for those terms. The Arm Glossary does not contain terms that are industry standard unless the Arm meaning differs from the generally accepted meaning.

See the Arm Glossary for more information: **https://developer.arm.com/glossary**.

1.3.2 Typographical conventions

Convention	Use
italic	Introduces citations.
bold	Highlights interface elements, such as menu names. Denotes signal names. Also used for terms in descriptive lists, where appropriate.
`monospace`	Denotes text that you can enter at the keyboard, such as commands, file and program names, and source code.
`monospace` **bold**	Denotes language keywords when used outside example code.
`monospace` <u>underline</u>	Denotes a permitted abbreviation for a command or option. You can enter the underlined text instead of the full command or option name.
`<and>`	Encloses replaceable terms for assembler syntax where they appear in code or code fragments. For example: `MRC p15, 0, <Rd>, <CRn>, <CRm>, <Opcode_2>`
SMALL CAPITALS	Used in body text for a few terms that have specific technical meanings, that are defined in the Arm® Glossary. For example, IMPLEMENTATION DEFINED, IMPLEMENTATION SPECIFIC, UNKNOWN, and UNPREDICTABLE.
Caution	This represents a recommendation which, if not followed, might lead to system failure or damage.
Warning	This represents a requirement for the system that, if not followed, might result in system failure or damage.
Danger	This represents a requirement for the system that, if not followed, will result in system failure or damage.
Note	This represents an important piece of information that needs your attention.
Tip	This represents a useful tip that might make it easier, better or faster to perform a task.
Remember	This is a reminder of something important that relates to the information you are reading.

1.4 Feedback

Arm welcomes feedback on this product and its documentation.

1.4.1 Feedback on this product

If you have any comments or suggestions about this product, contact your supplier and give:

- The product name.

- The product revision or version.

- An explanation with as much information as you can provide. Include symptoms and diagnostic procedures if appropriate.

1.4.2 Feedback on content

If you have comments on content, send an email to errata@arm.com and give:

- The title   Introduction to SVE2.

- The number 102340_0001.

- If applicable, the page number(s) to which your comments refer.

- A concise explanation of your comments.

Arm also welcomes general suggestions for additions and improvements.

Note

Arm tests the PDF only in Adobe Acrobat and Acrobat Reader and cannot guarantee the quality of the represented document when used with any other PDF reader.

2 Overview

This guide is a short introduction to version two of the Scalable Vector Extension (SVE2) for the Arm AArch64 architecture. In this guide, you can learn about the concept and main features of SVE2, the application domains of SVE2, and how SVE2 compares to SVE and to Neon. We also describe how to develop a program for an SVE2-enabled target.

2.1 Before you begin

This article assumes you are already familiar with the following concepts:

- Single Instruction Multi Data (SIMD)

- Neon

- Scalable Vector Extension (SVE)

If you are not familiar with these concepts, read:

- Introducing Neon for Armv8-A

- What is the Scalable Vector Extension (SVE)

- SVE and Neon coding compared

3 Introducing SVE2

This section introduces the Scalable Vector Extension version two (SVE2) of the Arm AArch64 architecture.

Following the development of the Neon architecture extension, which has a fixed 128-bit vector length for the instruction set, Arm designed the Scalable Vector Extension (SVE). SVE is a new Single Instruction Multiple Data (SIMD) instruction set that is used as an extension to AArch64, to allow for flexible vector length implementations. SVE improves the suitability of the architecture for High Performance Computing (HPC) applications, which require very large quantities of data processing.

SVE2 is a superset of SVE and Neon. SVE2 allows for more function domains in data-level parallelism. SVE2 inherits the concept, vector registers, and operation principles of SVE. SVE and SVE2 define 32 scalable vector registers. Silicon partners can choose a suitable vector length design implementation for hardware that varies between 128 bits and 2048 bits, at 128-bit increments. The advantage of SVE and SVE2 is that only one vector instruction set uses the scalable variables.

The SVE design concept enables developers to write and build software once, then run the same binaries on different AArch64 hardware with various SVE vector length implementations. The portability of the binaries means that developers do not have to know the vector length implementation for their system. Removing the requirement to rebuild binaries allows software to be ported more easily. In addition to the scalable vectors, SVE and SVE2 include:

- Per-lane predication

- Gather-load and scatter-store

- Speculative vectorization

These features help vectorize and optimize loops when you process large datasets.

The main difference between SVE2 and SVE is the functional coverage of the instruction set. SVE was designed for HPC and ML applications. SVE2 extends the SVE instruction set to enable data-processing domains beyond HPC and ML. The SVE2 instruction set can also accelerate the common algorithms that are used in the following applications:

- Computer vision

- Multimedia

- Long-Term Evolution (LTE) baseband processing

- Genomics

- In-memory database

- Web serving

- General-purpose software

To help compilers vectorize more effectively for these domains, SVE2 adds a vector-width-agnostic version of the Neon instructions in most of the integer Digital Signal Processing (DSP) and media processing functionality.

SVE and SVE2 both enable the collection and processing of a large amount of data.

SVE and SVE2 are not an extension of the Neon instruction set. Instead, SVE and SVE2 are redesigned for better data parallelism than Neon provides. However, the hardware logic of SVE and SVE2 overlays the Neon hardware implementation. When a microarchitecture supports SVE or SVE2, it also supports Neon. To use SVE and SVE2, software that runs on that microarchitecture must first use Neon.

Note

An SVE2 architecture overview is available to next generation architecture licensees, but is not publicly available yet.

4 SVE2 architecture fundamentals

This section introduces the basic architecture features that SVE and SVE2 share.

Like SVE, SVE2 is based on the scalable vectors. In addition to the existing register banks that Neon provides, SVE and SVE2 adds the following registers:

- 32 scalable vector registers, `Z0-Z31`
- 16 scalable predicate registers, `P0-P15`
    - One First Fault predicate Register (FFR)
- Scalable vector system control registers `ZCR_Elx`

Let's look at each of these in turn.

4.1 Scalable vector registers `z0-z31`

Each of the scalable vector registers, `Z0-Z31`, can be 128-2048 bits, with 128 bits increments. The bottom 128 bits are shared with the fixed 128-bit long `V0-V31` vectors of Neon.

The figure below shows the scalable vector registers `Z0-Z31`:
Figure 1 Scalable vector registers `z0-z31`

The scalable vectors can:

- Hold 64, 32, 16, and 8-bit elements
- Support integer, double-precision, single-precision, and half-precision floating-point elements
- Be configured with the vector length in each Exception level (EL)

4.2 Scalable predicate registers `P0-P15`

The figure below shows the scalable predicate registers `P0-P15`:
Figure 2 Scalable predicate registers `P0-P15`

The predicate registers are usually used as bit masks for data operations, where:

- Each predicate register is 1/8 of the `Zx` length.
- `P0-P7` are governing predicates for load, store, and arithmetic.
- `P8-P15` are extra predicates for loop management.
- First Fault Register (FFR) is for Speculative memory accesses.

If the predicate registers are not used as bit masks, they are used as operands.

4.3 Scalable vector system control registers `ZCR_Elx`

The figure below shows the scalable vector system control registers `ZCR_Elx`:

Figure 3 Scalable vector system control registers `ZCR_Elx`

The scalable vector system control registers indicate the SVE implementation features:

- The `ZCR_Elx.LEN` field is for the vector length of the current and lower exception levels
- Most bits are currently reserved for future use.

4.4 SVE2 assembly syntax

SVE2 follows the same assembly syntax format that SVE follows. The following instruction examples show this format.

Example 1:

```
LDFF1D {<Zt>.D}, <Pg>/Z, [<Xn|SP>, <Zm>.D, LSL #3]
```

Where:

- `<Zt>` are the vectors, `Z0-Z31`

- `D`, vector and predicate registers have known element type but unknown element numbers

- `<Pg>` are the predicates, `P0-P15`

- `Z` is the zeroing predication

- `<Zm>` is gather-scatter or vector addressing

Example 2:

```
ADD <Zdn>.<T>, <Pg>/M, <Zdn>.<T>, <Zm>.<T>
```

Where:

- `M` is the merging predication

Example 3

```
ORRS <Pd>.B, <Pg>.Z, <Pn>.B, <Pm>.B
```

Where:

- `S` is a new interpretation of predicate condition flags `NZCV`

- `Pg`, a predicate, is a "bit mask".

4.5 SVE2 architecture features

SVE2 inherits the following important SVE architecture features:

- Gather-load and scatter-store

  The flexible address mode in SVE allows vector base address or vector offset, which enables loading to a single vector register from non-contiguous memory locations. For example:

```
LD1SB  Z0.S, P0/Z, [Z1.S, #4]   // Gather load of signed bytes to active 32-bit
elements of Z0 from memory addresses generated by 32-bit vector base Z1 plus
immediate index #4.

LD1SB  Z0.D, P0/Z, [X0, Z1.D]   // Gather load of signed bytes to active elements of
Z0 from memory addresses generated by a 64-bit scalar base X0 plus vector index in
Z1.D.
```

- Per-lane predication

  To allow flexible operations on selected elements, SVE and SVE2 introduce 16 governing predicate registers, `P0-P15`, to indicate the valid operation on active lanes of the vectors. For example:

```
ADD Z0.D, P0/M, Z1.D, Z2.D  // Add the active elements Z1 and Z2 and put the result
in Z0. P0 indicates which elements of the operands are active and inactive. 'M'
after P0 indicates that the inactive element will be merged, meaning Z0 inactive
element will remain its original value before the ADD operation. If it was 'Z'
after P0, then it would mean that inactive element will be zeroed in the
destination vector register.
```

- Predicate-driven loop control and management

  Predicate-driven loop control and management is an efficient loop control feature. This feature allows loop heads and tails overhead, caused by the processing of partial vectors, to be removed by registering the active and inactive elements index in the predicate registers. This means that, in the next loop, only the active elements do the expected options. For example:

```
WHILEL0 P0.S, x8, x9  // Generate a predicate in P0 that starting from the lowest
numbered element is true while the incrementing value of the first, unsigned scalar
X8 operand is lower than the second scalar operand X9 and false thereafter, up to
the highest numbered element.
```

- Vector partitioning for software-managed speculation

  SVE improved the Neon vectorization restrictions on Speculative load. SVE introduces the first-fault vector load instructions, for example `LDRFF`, and the First-Fault predicate Registers (FFRs) to allow vector accesses to cross into invalid pages. For example:

```
LDFF1D Z0.D, P0/Z, [Z1.D, #0]  // Gather load with first-faulting behaviour of
doublewords to active elements of Z0 from memory addresses generated by the vector
base Z1 plus 0. Inactive elements will not read Device memory or signal faults and
are set to zero in the destination vector. Successful load to the valid memory will
set true to the first-fault register (FFR), and the first-faulting load will set
false to the according element and the rest elements in FFR.

RDFFR P0.B  // Read the first-fault register (FFR) and place in the destination
predicate without predication.
```

- Extended floating-point and bitwise horizontal reductions

  SVE enhances floating-point and bitwise horizontal reduction operations. Examples of these operations include in-order or tree-based floating-point sum. These operations trade off repeatability and performance. Here is some example code:

```
FADDP  Z0.S, P0/M, Z1.S, Z2.S  // Add pairs of adjacent floating-point elements
within each source vector Z1 and Z2, and interleave the results from corresponding
```

```
lanes. The interleaved result values are destructively placed in the first source
vector Z0.
```

5 New features in SVE2

This section introduces the new features that SVE2 adds to the Arm AArch64 architecture.

To achieve scalable performance, SVE2 builds on the foundations of SVE, allowing vector implementation up to 2048 bits.

In SVE2, many instructions are added that replicate existing instructions in Neon, including:

- Transformed Neon integer operations, for example, Signed absolute difference and accumulate (`SAB`) and Signed halving addition (`SHADD`).

- Transformed Neon widen, narrow, and pairwise operations, for example, Unsigned add long – bottom (`UADDLB`) and Unsigned add long – top (`UADDLT`).

There are changes in the element processing orders. SVE2 processes on interleaving even and odd elements, and Neon processed on low and high half elements for narrow or wider operations.

The following diagram illustrates the difference between the Neon and SVE2 processes:
Figure 4 Transformed Neon widen, narrow & pairwise operations

- Complex arithmetic, for example complex integer multiply-add with rotate (`CMLA`).

- Multi-precision arithmetic for large integer arithmetic and cryptography, for example, Add with carry long – bottom (`ADCLB`), Add carry long – top (`ADCLT`), and SM4 encryption and decryption (`SM4E`).

For backwards compatibility, Neon and VFP are required in the latest architectures. Although SVE2 includes some of the functions of SVE and Neon, SVE2 does not exclude the Neon presence on the chip.

SVE2 enables optimizations for emerging applications beyond the HPC market, for example, in Machine Learning (ML) (`UDOT` instruction), Computer Vision (`TBL` and `TBX` instructions), baseband networking (`CADD` and `CMLA` instructions), genomics (`BDEP` and `BEXT` instructions), and server (`MATCH` and `NMATCH` instructions).

SVE2 enhances the overall performance of the large volume of data operations of a general-purpose processor, without requiring other off-chip accelerators.

6 Program with SVE2

This section describes the software tools and libraries that support SVE2 application development. This section also describes how to develop your application for an SVE2-enabled target, run it on SVE2-enabled hardware, and emulate your application on any Armv8-A hardware.

6.1 Software and libraries support

To build an SVE or SVE2 application, you must choose a compiler that supports SVE and SVE2 features. GNU tools versions 8.0+ support SVE. Arm Compiler for Linux versions 18.0+ support SVE, and versions 20.0+ support both SVE and SVE2. Both GNU and Arm Compiler for Linux compilers support optimizing C/C++/Fortran code. The LLVM (open-source Clang) version 5 and onwards includes support for SVE, and version 9 and onwards includes support for SVE2. To find out what SVE or SVE2 features each version of the LLVM tools support, see the LLVM toolchain SVE support page.

Arm Performance Libraries are highly optimized for math routines, and can be linked to your application. Arm Performance Libraries versions 19.3+ support math libraries for SVE.

Arm Compiler for Linux, which is part of Arm Allinea Studio, consists of the Arm C/C++ Compiler, Arm Fortran Compiler, and Arm Performance Libraries.

6.2 How to program for SVE2

There are a few ways to write or generate SVE and SVE2 code. In this section of the guide, we explore some of them.

To write or generate SVE and SVE2 code, you can write assembly with SVE and SVE2 instructions, or use intrinsics in C/C++/Fortran applications. You can let compilers auto-vectorize your code, and use the SVE-optimized libraries. Let's look at each option.

- Write assembly code: You can write assembly files using SVE instructions, or use inline assembly in GNU style. For example:

```
        .globl   subtract_arrays          // -- Begin function
        .p2align        2
        .type    subtract_arrays,@function
subtract_arrays:                    // @subtract_arrays
        .cfi_startproc
// %bb.0:
        orr     w9, wzr, #0x400
        mov     x8, xzr
        whilelo p0.s, xzr, x9
.LBB0_1:                            // =>This Inner Loop Header: Depth=1
        ld1w    { z0.s }, p0/z, [x1, x8, lsl #2]
        ld1w    { z1.s }, p0/z, [x2, x8, lsl #2]
        sub     z0.s, z0.s, z1.s
        st1w    { z0.s }, p0, [x0, x8, lsl #2]
        incw    x8
```

```
        whilelo p0.s, x8, x9
        b.mi    .LBB0_1
// %bb.2:
        ret
.Lfunc_end0:
        .size   subtract_arrays, .Lfunc_end0-subtract_arrays
        .cfi_endproc T
```

To program in assembly, you must know the Application Binary Interface (ABI) standard updates for SVE and SVE2. The Procedure Call Standard for Arm Architecture (AAPCS) specifies the data types and register allocations and is most relevant to programming in assembly. The AAPCS requires that:

- o `Z0-Z7`, `P0-P3` are used for parameter and results passing.

- o `Z8-Z15`, `P4-P15` are callee-saved registers.

- o `Z16-Z31` are the corruptible registers.

- Use instruction functions: You can call instruction functions directly in high-level languages like C, C++, or Fortran that match corresponding SVE instructions. These instruction functions, which are sometimes referred to as intrinsics, are detailed in the ACLE (Arm C Language Extension) for SVE. Intrinsics are functions that match to corresponding instructions, so that programmers can directly call them in high-level languages like C, C++, or Fortran. The instruction functions are inserted with specific instructions after compilation. The ACLE for SVE document also includes the full list of instruction functions for SVE2 that programmers can use.

  For example, use the following code:

```
//intrinsic_example.c
#include <arm_sve.h>
svuint64_t uaddlb_array(svuint32_t Zs1, svuint32_t Zs2)
{
        // widening add of even elements
    svuint64_t result = svaddlb(Zs1, Zs2);
    return result;
}
```

  Compile the code using Arm C/C++ Compiler, as you can see here:

```
armclang -O3 -S -march=armv8-a+sve2 -o intrinsic_example.s intrinsic_example.c
```

  This generates the assembly code, as you can see here:

```
//instrinsic_example.s
uaddlb_array:                           // @uaddlb_array
        .cfi_startproc
// %bb.0:
        uaddlb  z0.d, z0.s, z1.s
        ret
```

This example uses Arm Compiler for Linux 20.0.

- Auto-vectorization: C/C++/Fortran compilers, for example Arm Compiler for Linux and GNU compilers for Arm platforms, generate the SVE and SVE2 code from C/C++/Fortran loops. To generate SVE or SVE2 code, select the appropriate compiler options for the SVE or SVE2 features. For example, with `armclang`, one option that enables SVE2 optimizations is `-march=armv8-a+sve2`. Combine `-march=armv8-a+sve2` with `-armpl=sve` if you want to use the SVE version of the libraries.

- Use libraries that are optimized for SVE and SVE2: There are already highly optimized libraries with SVE available, for example Arm Performance Libraries and Arm Compute Libraries. Arm Performance Libraries contain the highly optimized implementations for BLAS, LAPACK, FFT, sparse linear algebra, and libamath optimized mathematical functions. You must install Arm Allinea Studio and include `armpl.h` in your code to be able to link any of the ArmPL functions. To build the application with ArmPL using Arm Compiler for Linux, you must specify `-armpl=<arg>` on the command line. If you use the GNU tools, you must include the ArmPL installation path on command line, and specify the GNU equivalent to the Arm Compiler for Linux `-armpl=<arg>` option.

6.3 How to run an SVE and SVE2 application: Hardware and model

If you do not have access to SVE hardware, you can use models and emulators to develop your code. There are a few models and emulators to choose from:

- QEMU: Cross and native models, supporting modeling on Arm AArch64 platforms with SVE

- Fast Models: Cross platform models, supporting modeling on Arm AArch64 platforms with SVE. Architecture Envelope Model (AEM) with SVE2 support is available for lead partners.

- Arm Instruction Emulator (ArmIE): Runs directly on Arm platforms. Supports SVE, and supports SVE2 from version 19.2+.

7 Check your knowledge

- Which features did SVE2 inherit from SVE?

  SVE2 inherits the fundamental architecture features of SVE, including the vectors, system control registers, and instructions.

- What are the vectors for SVE2?

  SVE2 uses the same SVE `Z0-Z31` vectors, `P0-P15` predicate registers, and FFR predicate register that SVE uses.

- How many bits can SVE2 vectors have?

  `Z0-Z31` can be implemented from 128 bits up to 2048 bits, with 128 increment.

- What features does SVE2 enable, in addition to those added by SVE?

  SVE was designed for HPC. SVE2 extends the SVE instruction set to address the requirements in application areas like general-purpose software, web-serving server, computer vision, multi-media, LTE baseband process, genomics, and in-memory databases.

- What are the advantages of SVE2 compared to a traditional SIMD instruction set, for example Neon?

  The advantages of SVE2, compared to Neon, include:
    - SVE2 programs can be built once and run on hardware with various vector lengths.
    - SVE2 has more vectorization flexibility.
    - SVE2 extends the instruction set enabling more application areas.
